A transfer method, a photolithography method, a micro injection method, an embossing method, etc. have heretofore been known as methods of manufacturing a fine pattern. For example, in the transfer method, a fine pattern is formed by a method which includes the steps of depositing a metal film on an alignment layer formed on a substrate, selectively removing the metal film through photoetching using a mask pattern, and transferring the metal film on the substrate. This pattern forming method has various advantages. For example, the pattern size can be freely changed by the thickness of the metal film, because the alignment layer is utilized. Besides, there are no limitations on the material of the substrate. Thus, any substrate, which is not substantially influenced by the transfer conditions, can be used. Therefore, a metal pattern of high precision can be easily fabricated by this method. The transfer method, however, has a disadvantage in that the alignment layer is removed during the pattern forming step, and the substrate side surface is directly exposed. Thus, there is a problem in that the substrate is contaminated or the substrate is damaged by the removal of the alignment layer. This problem is remarkable in the case where the substrate surface is contaminated with dust or has fine concavities ba244e880a
